

16-Channel 14-Bit Voltage-Output DAC

Preliminary Technical Data

AD5517-1/AD5517-2/AD5517-3*

FEATURES

High Integration: 16-channel DAC in 12x12 mm² LFBGA
 Guaranteed Monotonic
 Low Power, SPI™, MICROWIRE™ and DSP-Compatible
 3-Wire Serial Interface
 Output Impedance 0.5Ω
 Output Voltage Range
 ± 2.5 V (AD5517-1)
 ± 5 V (AD5517-2)
 ± 10V (AD5517-3)
 Asynchronous $\overline{\text{RESET}}$ facility
 Daisy-Chaining Option
 Temperature Range -40°C to +85°C

APPLICATIONS

Level Setting
 Instrumentation
 Automatic Test Equipment
 Optical Networks
 Industrial Control Systems
 Data Acquisition
 Low Cost I/O

GENERAL DESCRIPTION

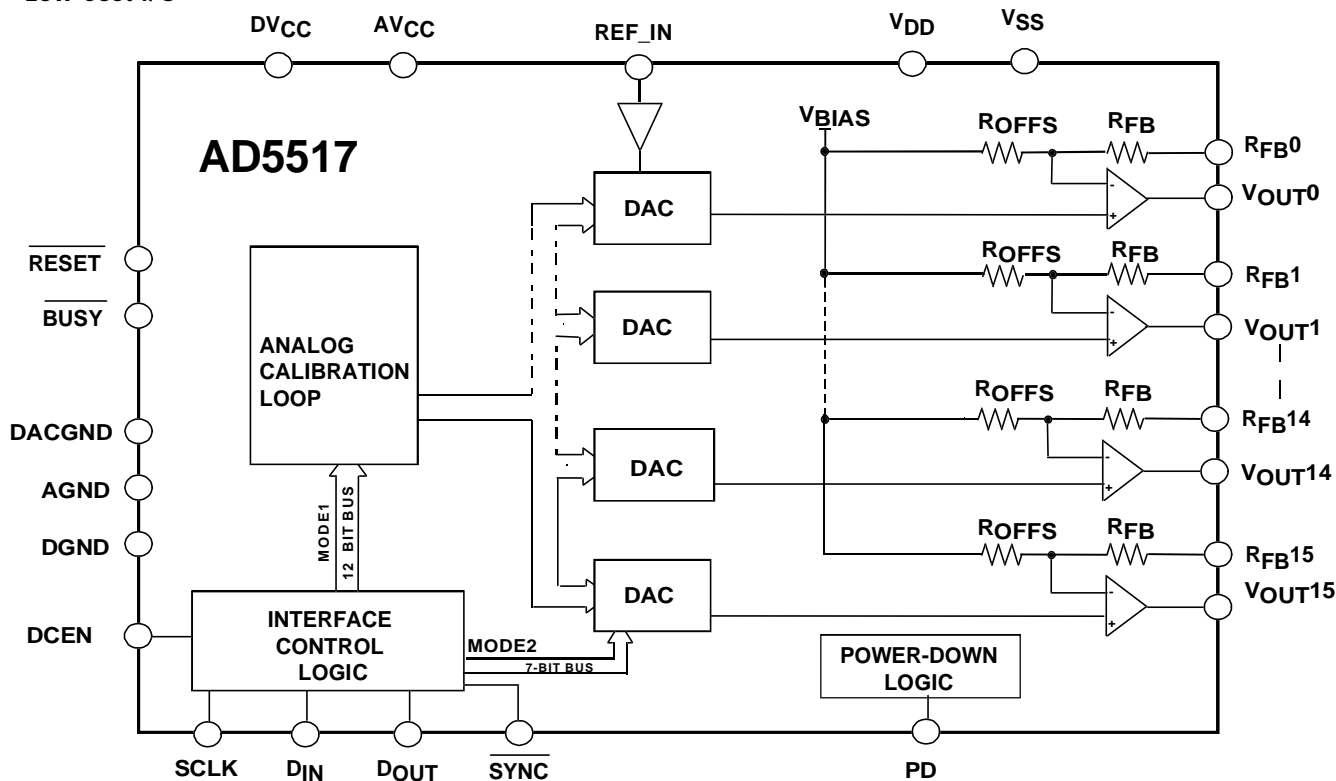

The AD5517 is a 16-channel voltage-output 14-bit DAC. The selected DAC register is written to via the 3-wire serial interface. DAC selection is accomplished via address bits A3-A0. 14-bit resolution is achieved by fine adjustment in Mode 2. The serial interface operates at clock rates up to 20 MHz and is compatible with standard SPI, MICROWIRE and DSP interface standards. The output voltage range is fixed at ±2.5 V (AD5517-1), ±5 V (AD5517-2) and ±10 V (AD5517-3). Access to the feedback resistor in each channel is provided via R_{FB0} to R_{BF15} pins.

The device is operated with AV_{CC} = 5 V ± 5%, DV_{CC} = 2.7 V to 5.25 V, V_{SS} = -4.75 V to -12 V and V_{DD} = 4.75 V to 12 V and requires a stable 2.5 V reference on REF_IN.

PRODUCT HIGHLIGHTS

- 16 14-bit DACs in one package, guaranteed monotonic.
- The AD5517 is available in a 74-lead LFBGA package with a body size of 12mm by 12mm.

FUNCTIONAL BLOCK DIAGRAM

*Protected by U.S. Patent Nos. 5,684,481 and 5,969,657; other patents pending.

NOTES:

¹Stresses above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only, and functional operation of the device at these or any other conditions above those listed in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

²Transient currents of up to 100mA will not cause SCR latch-up

ORDERING GUIDE

Model	Function	Output Voltage Span	Package Option
AD5517ABC-1	16 DACs	±2.5 V	74-lead LFBGA
AD5517ABC-2	16 DACs	±5 V	74-lead LFBGA
AD5517ABC-3	16 DACs	±10 V	74-lead LFBGA

CAUTION

ESD (electrostatic discharge) sensitive device. Electrostatic charges as high as 4000 V readily accumulate on the human body and test equipment and can discharge without detection. Although the AD5517 features proprietary ESD protection circuitry, permanent damage may occur on devices subjected to high energy electrostatic discharges. Therefore, proper ESD precautions are recommended to avoid performance degradation or loss of functionality.

PIN FUNCTION DESCRIPTION

Pin	Function
AGND(1-2)	Analog GND pins.
AV _{CC} (1-2)	Analog supply pins. Voltage range from 4.75 V to 5.25 V.
V _{DD} (1-2)	V _{DD} supply pins. Voltage range from 4.75 V to 12 V.
V _{SS} (1-2)	V _{SS} supply pins. Voltage range from -4.75 V to -12 V.
DGND	Digital GND pins.
DV _{CC}	Digital supply pins. Voltage range from 2.7 V to 5.25 V.
DACGND	Reference GND supply for all 16 DACs.
REF_IN	Reference input voltage for all 16 DACs.
V _{OUT} (0-15)	Analog output voltages from the 16 DAC channels.
R _{FB} (0-15)	Feedback Resistors. Access to the inverting inputs of the 16 output amplifiers allows remote sensing in force/sense applications. For nominal output voltage range connect each R _{FB} to it's corresponding V _{OUT} .
$\overline{\text{SYNC}}$	Active Low Input. This is the Frame Synchronisation signal for the serial interface. While $\overline{\text{SYNC}}$ is low, data is transferred in on the falling edge of SCLK.
SCLK	Serial Clock Input. Data is clocked into the shift register on the falling edge of SCLK. This operates at clock speeds up to 20 MHz.
D _{IN}	Serial Data Input. Data must be valid on the falling edge of SCLK.
D _{OUT}	Serial Data Output. D _{OUT} can be used for daisy-chaining a number of devices together or for reading back the data in the shift register for diagnostic purposes. Data is clocked out on D _{OUT} on the rising edge of SCLK and is valid on the falling edge of SCLK.
DCEN ¹	Active High Control Input. This pin is tied high to enable Daisy-Chain Mode.
RESET ²	Active Low Control Input. This resets all DAC registers to their mid-scale value.
PD	Active High Control Input. All DACs go into power-down mode when this pin is high. The DAC outputs go into a high-impedance state and the power dissipation drops to TBD.
$\overline{\text{BUSY}}$	Active Low Output. This signal tells the user that the analog calibration loop is active. It goes low during conversion. The duration of the pulse on $\overline{\text{BUSY}}$ determines the maximum DAC update rate, f _{UPDATE} .

NOTES:

¹Internal Pull-down device on this logic input. Therefore it can be left floating and will default to a logic low condition.

²Internal Pull-up device on this logic input. Therefore it can be left floating and will default to a logic high condition.

TERMINOLOGY**Integral Nonlinearity (INL)**

This is a measure of the maximum deviation from a straight line passing through the endpoints of the DAC transfer function. It is expressed in LSBs.

Differential Nonlinearity (DNL)

Differential Nonlinearity (DNL) is the difference between the measured change and the ideal 1 LSB change between any two adjacent codes. A specified DNL of ± 1 LSB maximum ensures monotonicity.

Bipolar Zero Error

Bipolar zero error is the deviation of the DAC output from the ideal midscale of 0 V. It is measured with 10...00 loaded to the DAC. It is expressed in LSBs.

Positive Full-Scale Error

This is the error in the DAC output voltage with all 1s loaded to the DAC. Ideally the DAC output voltage, with all 1s loaded to the DAC registers, should be REF_IN (AD5517-1), 2 REF_IN (AD5517-2) and 4 REF_IN (AD5517-3). It is expressed in LSBs.

Negative Full-Scale Error

This is the error in the DAC output voltage with all 0s loaded to the DAC. Ideally the DAC output voltage, with all 0s loaded to the DAC registers, should be -REF_IN (AD5517-1), -2 REF_IN (AD5517-2) and -4 REF_IN (AD5517-3). It is expressed in LSBs.

Output Temperature Coefficient

This is a measure of the change in analog output with changes in temperature. It is expressed in ppm/°C.

DC Power-Supply Rejection Ratio

DC Power-Supply Rejection Ratio (PSRR) is a measure of the change in analog output for a change in supply voltage (V_{DD} and V_{SS}). It is expressed in dBs. V_{DD} and V_{SS} are varied $\pm 5\%$.

DC Crosstalk

This the DC change in the output level of one DAC at mid-scale in response to a full-scale code change (all 0s to all 1s and vice versa) and output change of another DAC. It is expressed in μ V.

Output Settling Time

This is the time taken from when the last data bit is clocked into the DAC until the output has settled to within ± 0.5 LSB of its final value.

Digital-to-Analog Glitch Impulse

This is the area of the glitch injected into the analog output when the code in the DAC register changes state. It is specified as the area of the glitch in nV-secs when the digital code is changed by 1 LSB at the major carry transition (011...11 to 100...00 or 100...00 to 011...11).

Digital Crosstalk

This is the glitch impulse transferred to the output of one DAC at mid-scale while a full-scale code change (all 1s to all 0s and vice versa) is being written to another DAC. It is expressed in nV-secs.

Analog Crosstalk

This the area of the glitch transferred to the output (V_{OUT}) of one DAC due to a full-scale change in the output (V_{OUT}) of another DAC. The area of the glitch is expressed in nV-secs.

Digital Feedthrough

This is a measure of the impulse injected into the analog outputs from the digital control inputs when the part is not being written to, i.e. \overline{SYNC} is high. It is specified in nV-secs and is measured with a worst-case change on the digital input pins, e.g. from all 0s to all 1s and vice versa.

Output Noise Spectral Density

This is a measure of internally generated random noise. Random noise is characterized as a spectral density (voltage per root Hertz). It is measured in $nV/(Hz)^{1/2}$.

FUNCTIONAL DESCRIPTION

The AD5517 consists of 16 14-bit DACs in a single package. A single reference input pin (REF_IN) is used to provide a 2.5 V reference for all 16 DACs. To update a DAC's output voltage an 18-bit word is written to the part via the 3-wire serial interface. This 18-bit word consists of 2 mode bits, 4 address bits and 12 data bits as shown in Figure 4. Once the serial write is complete the selected DAC converts the code. The output amplifiers translate the 0 - 2.5 V DAC output range to give a ± 5 V range at the output pins V_{OUT0} to V_{OUT15}.

SERIAL INTERFACE

DCEN (Daisy-Chain Enable) determines whether the serial interface is in Daisy-Chain Mode or Stand-Alone Mode. In both modes SYNC is an edge-triggered input that acts as a frame synchronization signal and chip enable. Data can only be transferred into the device while SYNC is low. To start the serial data transfer, SYNC should be taken low observing the minimum SYNC falling to SCLK falling edge setup time, t₃.

Stand-Alone Mode (DCEN = 0)

After SYNC goes low, serial data will be shifted into the device's input shift register on the falling edges of SCLK for 18 clock pulses. After the falling edge of the 18th SCLK pulse, data will automatically be transferred from the input shift register to the addressed DAC. BUSY goes low indicating that conversion has started. All SCLK pulses will be ignored while BUSY is low. At the end of a conversion BUSY goes high indicating that the update of the addressed DAC is complete. It is recommended that SCLK is not pulsed while BUSY is low. See the timing diagram in Figure 1.

SYNC must be taken high and low again for further serial data transfer. SYNC may be taken high after the falling edge of the 18th SCLK pulse, observing the minimum SCLK falling edge to SYNC rising edge time, t₆. If SYNC is taken high before the 18th falling edge of SCLK, the data transfer will be aborted and the addressed DAC will not be updated.

Daisy-Chain Mode (DCEN = 1)

In Daisy-Chain Mode the internal gating on SCLK is disabled. The SCLK is continuously applied to the input shift register when SYNC is low. If more than 18 clock pulses are applied, the data ripples out of the shift register and appears on the D_{OUT} line. This data is clocked out on the rising edge of SCLK and is valid on the falling edge. By connecting this line to the D_{IN} input on the next device in the chain, a multi-device interface is constructed. 18 clock pulses are required for each device in the system. Therefore, the total number of clock cycles must equal 18N where N is the total number of devices in the chain. See the timing diagram in Figure 2.

When the serial transfer to all devices is complete, SYNC should be taken high. This prevents any further data being clocked into the input shift register. A burst clock containing the exact number of clock cycles may be used and SYNC taken high some time later. After the rising edge of SYNC, data is automatically transferred from each device's input shift register to the addressed DAC. BUSY goes low indicating that conversion has started. All SCLK pulses will be ignored while BUSY is low. At the end of a conversion BUSY goes high indicating that the update of the addressed DACs is complete. It is recommended that SCLK is not pulsed while BUSY is low.
