$\dagger$ Burn-in is available on commercial and industrial temperature range parts in CerDIP, plastic DIP, and TO-can packages.
For availability and burn-in information on SO and PLCC packages, contac your local sales office.

## GENERAL DESCRIPTION

The OP-27 precision operational amplifier combines the low offset and drift of the OP-07 with both high speed and low noise. Offsets down to $25 \mu \mathrm{~V}$ and drift of $0.6 \mu \mathrm{~V} /{ }^{\circ} \mathrm{C}$ maximum make the OP-27 ideal for precision instrumentation applications. Exceptionally low noise, $\mathrm{e}_{\mathrm{n}}=3.5 \mathrm{nV} / \sqrt{\mathrm{Hz}}$, at 10 Hz , a low $1 / \mathrm{f}$ noise corner frequency of 2.7 Hz , and high gain ( 1.8 million), allow accurate high-gain amplification of low-level
signals. A gain-bandwidth product of 8 MHz and a $2.8 \mathrm{~V} / \mu \mathrm{sec}$ slew rate provides excellent dynamic accuracy in high-speed data-acquisition systems.

A low input bias current of $\pm 10 \mathrm{nA}$ is achieved by use of a bias-current-cancellation circuit. Over the military temperature range, this circuit typically holds $\mathrm{I}_{\mathrm{B}}$ and $\mathrm{I}_{\mathrm{OS}}$ to $\pm 20 \mathrm{nA}$ and 15 nA respectively
The output stage has good load driving capability. A guaranteed swing of $\pm 10 \mathrm{~V}$ into $600 \Omega$ and low output distortion make the OP-27 an excellent choice for professional audio applications.
PSRR and CMRR exceed 120dB. These characteristics, coupled with long-term drift of $0.2 \mu \mathrm{~V} /$ month, allow the circuit designer to achieve performance levels previously attained only by discrete designs.

SIMPLIFIED SCHEMATIC

## OP-27

Low cost, high-volume production of OP-27 is achieved by using an on-chip zener-zap trimming network. This reliable and stable offset trimming scheme has proved its effectiveness over many years of production history.

The OP-27 provides excellent performance in low-noise high-accuracy amplification of low-level signals. Applica tions include stable integrators, precision summing amplifiers, precision voltage-threshold detectors, comparators and professional audio circuits such as tape-head and microphone preamplifiers.
The OP-27 is a direct replacement for 725, OP-06, OP-07 and OP-05 amplifiers; 741 types may be directly replaced by removing the 741's nulling potentiometer

| 8 -Pin SO (S) | 158 | 43 | ${ }^{\circ} \mathrm{CW}$ |

NOTES:

1. For supply voltages less than $\pm 22 \mathrm{~V}$, the absolute maximum input voltage is
equal to the supply voltage.
2. The OP-27's inputs are protected by back-to-back diodes. Current limiting resistors are not used in order to achieve low noise. If differential input voltage exceeds $\pm 0.7 \mathrm{~V}$, the input current should be limited to 25 mA .
3. $\theta_{\text {iA }}$ is specified for worst case mounting conditions, i...,$\theta_{j A}$ is specified for device in socket for TO, CerDIP, P-DIP, and LCC packages; $\Theta_{j A}$ is specilied for device soldered to printed circuit board for SO package. otherwise noted.

ELECTRICAL CHARACTERISTICS at $\mathrm{V}_{\mathrm{S}}= \pm 15 \mathrm{~V}, \mathrm{~T}_{\mathrm{A}}=25^{\circ} \mathrm{C}$, unless otherwise noted.

Range
NOTES:
Input offset voltage measurements are performed $\sim 0.5$ seconds after application of power. A/E grades guaranteed fully warmed-up.
Long-term input offset voltage stability refers to the average trend line of $V_{0 S}$ vs. Time over extended periods after the first 30 days of operation
days are typically $2.5 \mu \mathrm{~V}$ - refer to typical performance curve 3. Sample tested.

Guaranteed by design.
5. See test circuit and frequency response curve for 0.1 Hz to 10 Hz tester

See test circuit-for current noise measurement
7. Guaranteed by input bias current.

## APPLICATIONS INFORMATION

OP-27 Series units may be inserted directly into 725, OP-06 OP-07 and OP-05 sockets with or without removal of external compensation or nulling components. Additionally, the OP27 may be fitted to unnulled 741-type sockets; however, if conventional 741 nulling circuitry is in use, it should be modified or removed to ensure correct OP-27 operation. OP-27 offset voltage may be nulled to zero (or other desired setting) using a potentiometer (see Offset Nulling Circuit).

The OP-27 provides stable operation with load capacitances of up to 2000 pF and $\pm 10 \mathrm{~V}$ swings; larger capacitances should be decoupled with a $50 \Omega$ resistor inside the feedback loop. The OP-27 is unity-gain stable.

Thermoelectric voltages generated by dissimilar metals at the input terminal contacts can degrade the drift performance. Best operation will be obtained when both input contacts are maintained at the same temperature.

## OFFSET VOLTAGE ADJUSTMENT

The input offset voltage of the OP-27 is trimmed at wafer level. However, if further adjustment of $V_{O S}$ is necessary, a $10 \mathrm{k} \Omega$ trim potentiometer may be used. TCV os is not degraded

LOW-FREQUENCY NOISE

PSRR vs FREQUENCY

(see Offset Nulling Circuit). Other potentiometer values from $1 \mathrm{k} \Omega$ to $1 \mathrm{M} \Omega$ can be used with a slight degradation ( 0.1 to $0.2 \mu \mathrm{~V} /{ }^{\circ} \mathrm{C}$ ) of TCV ${ }^{\circ}$. Trimming to a value other than zero creates a drift of approximately ( $\mathrm{V}_{0 S} / 300$ ) $\mu \mathrm{V} /{ }^{\circ} \mathrm{C}$. For example, the change in TCV Os will be $0.33 \mu \mathrm{~V} /{ }^{\circ} \mathrm{C}$ if $\mathrm{V}_{\text {Os }}$ is adjusted to $100 \mu \mathrm{~V}$. The offset-voltage adjustment range with a $10 \mathrm{k} \Omega$ potentiometer is $\pm 4 \mathrm{mV}$. If smaller adjustment range is required, the nulling sensitivity can be reduced by using a smaller pot in conjuction with fixed resistors. For example, the network below will have $\mathrm{a} \pm 280 \mu \mathrm{~V}$ adjustment range.

## NOISE MEASUREMENTS

To measure the $80 n \vee$ peak-to-peak noise specification of the OP-27 in the 0.1 Hz to 10 Hz range, the following precautions must be observed:
(1) The device has to be warmed-up for at least five minutes As shown in the warm-up drift curve, the offset voltage
typically changes $4 \mu \mathrm{~V}$ due to increasing chip temperature after power-up. In the 10 -second measurement interval, these temperature-induced effects can exceed tens-ofnanovolts.
(2) For similar reasons, the device has to be well-shielded from air currents. Shielding minimizes thermocouple effects.
(3) Sudden motion in the vicinity of the device can also "feedthrough" to increase the observed noise.
(4) The test time to measure 0.1 Hz -to- 10 Hz noise should not exceed 10 seconds. As shown in the noise-testerfrequencyresponse curve, the 0.1 Hz corner is defined by only one zero. The test time of 10 seconds acts as an additional zero to eliminate noise contributions from the frequency band below 0.1 Hz
(5) A noise-voltage-density test is recommended when measuring noise on a large number of units. A 10 Hz noise-voltage-density measurement will correlate wel with a $0.1 \mathrm{~Hz}-\mathrm{to}-10 \mathrm{~Hz}$ peak-to-peak noise reading, since both results are determined by the white noise and the location of the $1 / \mathrm{f}$ corner frequency.

## UNITY-GAIN BUFFER APPLICATIONS

When $R_{t} \leq 100 \Omega$ and the input is driven with a fast, large signal pulse ( $>1 \mathrm{~V}$ ), the output waveform will look as shown in the pulsed operation diagram below
During the fast feedthrough-like portion of the output, the input protection diodes effectively short the output to the input and a current, limited only by the output short-circuit protection, will be drawn by the signal generator. With $R_{f} \geq 500 \Omega$, the output is capable of handling the current requirements ( $\mathrm{I}_{\mathrm{L}} \leq 20 \mathrm{~mA}$ at 10 V ); the amplifier will stay in its active mode and a smooth transition will occur.
When $R_{f}>2 k \Omega$, a pole will be created with $R_{f}$ and the amplifier's input capacitance ( 8 pF ) that creates additional phase shift and reduces phase margin. A small capacitor ( 20 to 50 pF ) in parallel with $\mathrm{R}_{\mathrm{f}}$ will eliminate this problem

## PULSED OPERATION

## COMMENTS ON NOISE

The OP-27 is a very low-noise monolithic op amp. The out standing input voltage noise characteristics of the OP-27 are achieved mainly by operating the input stage at a high quiescent current. The input bias and offset currents, which would normally increase, are held to reasonable values by the input-
bias-current cancellation circuit. The OP-27A/E has $I_{B}$ and los of only $\pm 40 n \mathrm{~A}$ and $35 n \mathrm{~A}$ respectively at $25^{\circ} \mathrm{C}$. This is particularly important when the input has a high sourceresistance. In addition, many audio amplifier designers prefer to use direct coupling. The high $I_{B}, V_{O S}, T C V_{O S}$ of previous designs have made direct coupling difficult, if not impossible, to use.
Voltage noise is inversely proportional to the square-root of bias current, but current noise is proportional to the squareroot of bias current. The OP-27's noise advantage disappears when high source-resistors are used. Figures 1, 2, and 3 compare OP-27 observed total noise with the noise performance of other devices in different circuit applications.
Total noise $=\left[(\text { Voltage noise })^{2}+\left(\text { current noise } \times \mathbf{R}_{\mathrm{S}}\right)^{2}+\right.$ (resistor noise) $\left.{ }^{2}\right]^{1 / 2}$
Figure 1 shows noise-versus-source-resistance at 1000 Hz . The same plot applies to wideband noise. To use this plot, just multiply the vertical scale by the square-root of the bandwidth.

At $R_{S}<1 \mathrm{k} \Omega$, the OP-27's low voltage noise is maintained. With $R_{S}>1 \mathrm{k} \Omega$, total noise increases, but is dominated by the resistor noise rather than current or voltage noise. It is only beyond $R_{S}$ of $20 \mathrm{k} \Omega$ that current noise starts to dominate. The argument can be made that current noise is not important for applications with low-to-moderate source resistances. The crossover between the OP-27 and OP-07 and OP-08 noise occurs in the $15-t o-40 \mathrm{k} \Omega$ region.
Figure 2 shows the 0.1 Hz -to- 10 Hz peak-to-peak noise. Here the picture is less favorable; resistor noise is negligible, current noise becomes important because it is inversely proportional to the square-root of frequency. The crossover with the OP-07 occurs in the $3-t 0-5 k \Omega$ range depending on whether balanced or unbalanced source resistors are used (at $3 k \Omega$ the $I_{B}$, los error also can be three times the $\left.V_{O S} s p e c.\right)$.

## OP-27

Therefore, for low-frequency applications, the OP-07 is better than the OP-27/37 when $R_{S}>3 k \Omega$. The only exception is when gain error is important. Figure 3 illustrates the 10 Hz noise. As expected, the results are between the previous two figures.
For reference, typical source resistances of some signal sources are listed in Table 1

Table 1

| Device | SOURCE IMPEDANCE | COMMENTS |
| :---: | :---: | :---: |
| Strain gauge | $<500 \Omega \quad$ T | Typically used in low-frequency applications. |
| Magnetic tapehead | <1500』 | Low $I_{B}$ very important to reduce self-magnetization problems when direct coupling is used. OP-27 $I_{B}$ can be neglected. |
| Magnetic phonograph cartridges | <1500 | Similar need for low $\mathrm{I}_{\mathrm{B}}$ in direct coupled applications. OP-27 will not introduce any self-magnetization problem. |
| Linear variable differential transformer | <1500 ${ }^{\text {U }}$ | Used in rugged servo-feedback applications. Bandwidth of interest is 400 Hz to 5 kHz . |
|  | * |  |
| OPEN-LOOP GAIN |  |  |
| FREQUENCY AT: | OP-07 | 7 OP-27 OP-37 |
| 3 Hz | 100 dB | B 124dB 125dB |
| 10 Hz | 100 dB | $\mathrm{B} \quad 120 \mathrm{~dB}$ 125dB |
| 30 Hz | 90 dB | B 110dB 124dB |

## AUDIO APPLICATIONS

The following applications information has been abstracted from a PMI article in the 12/20/80 issue of Electronic Design magazine and updated
Figure 4 is an example of a phono pre-amplifier circuit using the OP-27 for $A_{1} ; R_{1}-R_{2}-C_{1}-C_{2}$ form a very accurate RIAA network with standard component values. The popular method to accomplish RIAA phono equalization is to employ frequency-dependent feedback around a high-quality gain block. Properly chosen, an RC network can provide the three necessary time constants of 3180,318 , and $75 \mu \mathrm{~s} .{ }^{1}$
For initial equalization accuracy and stability, precision metal-film resistors and film capacitors of polystyrene or polypropylene are recommended since they have low voltage coefficients, dissipation factors, and dielectric absorption. ${ }^{4}$ (High-K ceramic capacitors should be avoided here, though low-K ceramics - such as NPO types, which have excellent dissipation factors, and somewhat lower dielectric absorptioncan be considered for small values.)

The OP-27 brings a $3.2 \mathrm{nV} / \sqrt{\mathrm{Hz}}$ voltage noise and 0.45 $\mathrm{pA} / \sqrt{\mathrm{Hz}}$ current noise to this circuit. To minimize noise from other sources, $R_{3}$ is set to a value of 100 2 , which generates a voltage noise of $1.3 \mathrm{nV} / \sqrt{\mathrm{Hz}}$. The noise increases the $3.2 \mathrm{nV} / \sqrt{\mathrm{Hz}}$ of the amplifier by only 0.7 dB . With a $1 \mathrm{k} \Omega$ source, the circuit noise measures 63 dB below a 1 mV reference level, unweighted, in a 20 kHz noise bandwidth.
Gain (G) of the circuit at 1 kHz can be calculated by the expression:

$$
G=0.101\left(1+\frac{R_{1}}{R_{3}}\right)
$$

For the values shown, the gain is just under 100 (or 40 dB ) Lower gains can be accommodated by increasing $R_{3}$, but gains higher than 40 dB will show more equalization errors because of the 8 MHz gain-bandwidth of the OP-27.
This circuit is capable of very low distortion over its entire range, generally below $0.01 \%$ at levels up to 7 V rms. At 3 V output levels, it will produce less than $0.03 \%$ total harmonic distortion at frequencies up to 20 kHz .
Capacitor $\mathrm{C}_{3}$ and resistor $\mathrm{R}_{4}$ form a simple-6dB-per-octave rumble filter, with a corner at 22 Hz . As an option, the switchselected shunt capacitor $\mathrm{C}_{4}$, a nonpolarized electrolytic, bypasses the low-frequency rolloff. Placing the rumble filter's high-pass action after the preamp has the desirable result of discriminating against the RIAA-amplified lowfrequency noise components and pickup-produced lowfrequency disturbances.
A preamplifier for NAB tape playback is similar to an RIAA phono preamp, though more gain is typically demanded, along with equalization requiring a heavy low-frequency boost. The circuit in Fig. 4 can be readily modified for tape use, as shown by Fig. 5 .

While the tape-equalization requirement has a flat highfrequency gain above $3 \mathrm{kHz}\left(\mathrm{T}_{2}=50 \mu \mathrm{~s}\right.$ ), the amplifier need not be stabilized for unity gain. The decompensated OP-37 provides a greater bandwidth and slew rate. For many applications, the idealized time constants shown may require trimming of $\mathrm{R}_{1}$ and $\mathrm{R}_{2}$ to optimize frequency response for nonideal tape-head performance and other factors. ${ }^{5}$

The network values of the configuration yield a 50 dB gain at 1 kHz , and the dc gain is greater than 70 dB . Thus, the worstcase output offset is just over 500 mV . A single $0.47 \mu \mathrm{~F}$ output capacitor can block this level without affecting the dynamic range.
The tape head can be coupled directly to the amplifier input, since the worst-case bias current of 80 nA with a $400 \mathrm{mH}, 100$ $\mu \mathrm{in}$. head (such as the PRB2H7K) will not be troublesome. One potential tape-head problem is presented by amplifier bias-current transients which can magnetize a head. The OP-27 and OP-37 are free of bias-current transients upon power up or power down. However, it is always advantageous to control the speed of power supply rise and fall, to eliminate transients
In addition, the dc resistance of the head should be carefully controlled, and preferably below $1 \mathrm{k} \Omega$. For this configuration, the bias-current-induced offset voltage can be greater than the $100 \mu \mathrm{~V}$ maximum offset if the head resistance is not sufficiently controlled.
A simple, but effective, fixed-gain transformerless microphone preamp (Fig.6) amplifies differential signals from lowimpedance microphones by 50 dB , and has an input impedance of $2 k \Omega$. Because of the high working gain of the circuit, an OP- 37 helps to preserve bandwidth, which will be 110 kHz . As the OP-37 is a decompensated device (minimum stable gain of 5 ), a dummy resistor, $R_{p}$, may be necessary, if the microphone is to be unplugged. Otherwise the $100 \%$ feed back from the open input may cause the amplifier to oscillate.
Common-mode input-noise rejection will depend upon the match of the bridge-resistor ratios. Either close-tolerance ( $0.1 \%$ ) types should be used, or $R_{4}$ should be trimmed for best CMRR. All resistors should be metal-film types for best stability and low noise.
Noise performance of this circuit is limited more by the input resistors $R_{1}$ and $R_{2}$ than by the op amp, as $R_{1}$ and $R_{2}$ each generate a $4 \mathrm{nV} / \sqrt{\mathrm{Hz}}$ noise, while the op amp generates a $3.2 \mathrm{nV} / \sqrt{\mathrm{Hz}}$ noise. The rms sum of these predominant noise sources will be about $6 \mathrm{nV} / \sqrt{\mathrm{Hz}}$, equivalent to $0.9 \mu \mathrm{~V}$ in a 20 kHz noise bandwidth, or nearly 61 dB below a 1 mV input signal. Measurements confirm this predicted performance.

Figure 6

For applications demanding appreciably lower noise, a highquality microphone-transformer-coupled preamp (Fig. 7) incorporates the internally-compensated OP-27. $T_{1}$ is a JE-115K-E 150 $/$ /15k $\Omega$ transformer which provides an optimum source resistance for the OP-27 device. The circuit has an overall gain of 40 dB , the product of the transformer's voltage setup and the op amp's voltage gain.

Gain may be trimmed to other levels, if desired, by adjusting $\mathrm{R}_{2}$ or $\mathrm{R}_{1}$. Because of the low offset voltage of the OP-27, the output offset of this circuit will be very low, 1.7 mV or less, for a 40 dB gain. The typical output blocking capacitor can be
eliminated in such cases, but is desirable for higher gains to eliminate switching transients.
Capacitor $\mathrm{C}_{2}$ and resistor $\mathrm{R}_{2}$ form a $2 \mu$ s time constant in this circuit, as recommended for optimum transient response by the transformer manufacturer. With $\mathrm{C}_{2}$ in use, $\mathrm{A}_{1}$ must have unity-gain stability. For situations where the $2 \mu$ s time constant is not necessary, $\mathrm{C}_{2}$ can be deleted, allowing the faster OP-37 to be employed.
Some comment on noise is appropriate to understand the capability of this circuit. A $150 \Omega$ resistor and $R_{1}$ and $R_{2}$ gain resistors connected to a noiseless amplifier will generate 220 nV of noise in a 20 kHz bandwidth, or 73 dB below a 1 mV reference level. Any practical amplifier can only approach this noise level; it can never exceed it. With the OP-27 and $\mathrm{T}_{1}$ specified, the additional noise degradation will be close to 3.6 dB (or -69.5 referenced to 1 mV ).
