

A/D Converter with Bar Graph Display Output

FEATURES

- Bipolar A/D Conversion
- 2.5% Resolution
- Direct LCD Display Drive
- 'Thermometer' Bar or Dot Display
- 40 Data Segments Plus Zero
- Overage Plus Polarity Indication
- Precision On-Chip Reference 35ppm/°C
- Differential Analog Input
- Low Input Leakage 10pA
- Display Flashes on Overage
- Display Hold Mode
- Auto-Zero Cycle Eliminates Zero Adjust Potentiometer
- 9V Battery Operation
- Low Power Consumption 1.1mW
- 20mV to 2.0 V Full-Scale Operation
- Non-Multiplexed LCD Drive for Maximum Viewing Angle

GENERAL DESCRIPTION

In many applications a graphical display is preferred over a digital display. Knowing a process or system operates, for example, within design limits is more valuable than a direct system variable readout. A bar or moving dot display supplies information precisely without requiring further interpretation by the viewer.

The TC826 is a complete analog-to-digital converter with direct liquid crystal (LCD) display drive. The 40 LCD data segments plus zero driver give a 2.5% resolution bar display. Full-scale differential input voltage range extends from 20mV to 2V. The TC826 sensitivity is 500µV. A low drift 35 ppm/°C internal reference, LCD backplane oscillator and driver, input polarity LCD driver, and overrange LCD driver make designs simple and low cost. The CMOS design required only 125µA from a 9V battery. In +5V systems a TC7660 DC to DC converter can supply the -5V supply. The differential analog input leakage is a low 10pA.

Two display formats are possible. The BAR mode display is like a 'thermometer' scale. The LCD segment driver that equals the input plus all below it are on. The DOT mode activates only the segment equal to the input. In either mode the polarity signal is active for negative input signals. An overrange input signal causes the display to flash and activates the overrange annunciator. A hold mode can be selected that freezes the display and prevents updating.

The dual slope integrating conversion method with auto-zero phase maximizes noise immunity and eliminates zero-scale adjustment potentiometers. Zero-scale drift is a low 5 µV/°C. Conversion rate is typically 5 per second and is adjustable by a single external resistor.

A compact, 0.5" square, flat package minimizes PC board area. The high pin count LSI package makes multiplexed LCD displays unnecessary. Low cost, direct drive LCD displays offer the widest viewing angle and are readily available. A standard display is available now for TC826 prototyping work.

PIN DESCRIPTION

Pin No.

64-Pin

PQFP

Pin No.	Symbol	Description
1	NC	
2	ANALOG COMMON	Establishes the internal analog ground point. Analog common is set to 2.9V below the positive supply by an internal zener reference circuit. The voltage difference between V_{DD} and analog-common can be used to supply the TC826 voltage reference input at REF IN (Pin 5).
3	+IN	Positive analog signal input.
4	-IN	Negative analog signal input.
5	REF IN	Reference voltage positive input. Measured relative to analog-common. REF IN \approx Full-Scale/2.
6	CREF ⁺	Reference capacitor connection.
7	CREF ⁻	Reference capacitor connection.
8	V_{DD}	Positive supply terminal.
9	V_{BUF}	Buffer output. Integration resistor connection.
10	C_{AZ}	Negative comparator input. Auto-zero capacitor connection.
11	V_{INT}	Integrator output. Integration capacitor connection.
12	V_{SS}	Negative supply terminal.
13	OSC1	Oscillator resistor (ROSC) connection.
14	OSC2	Oscillator resistor (ROSC) connection.
15	BP	LCD Backplane driver.

Figure 1. Typical TC826 Circuit Connection

TC826

DUAL SLOPE CONVERSION PRINCIPLES

The TC826 is a dual slope, integrating analog-to-digital converter. The conventional dual slope converter measurement cycle has two distinct phases:

- Input Signal Integration
- Reference Voltage Integration (Deintegration)

The input signal being converted is integrated for a fixed time period (T_{SI}). Time is measured by counting clock pulses. An opposite polarity constant reference voltage is then integrated until the integrator output voltage returns to zero. The reference integration time is directly proportional to the input signal (T_{RI}). (Figure 2).

In a simple dual slope converter a complete conversion requires the integrator output to 'ramp-up' and 'ramp-down'.

A simple mathematical equation relates the input signal reference voltage and integration time:

$$\frac{1}{RC} \int_0^{T_{SI}} V_{IN}(t) dt = \frac{V_R T_{RI}}{RC}$$

Where:

V_R = Reference Voltage

V_{SI} = Signal Integration Time (Fixed)

T_{RI} = Reference Voltage Integration Time (Variable)

For a constant V_{IN}: $V_{IN} = V_R \frac{T_{RI}}{T_{SI}}$

The dual slope converter accuracy is unrelated to the integrating resistor and capacitor values as long as they are stable during a measurement cycle. An inherent benefit is noise immunity. Noise spikes are integrated or averaged to zero during the integration periods. Integrating ADCs are immune to the large conversion errors that plague successive approximation converters in high noise environments. Interfering signals with frequency components at multiples of the averaging period will be attenuated. (Figure 3.)

The TC826 converter improves the conventional dual slope conversion technique by incorporating an auto-zero phase. This phase eliminates zero-scale offset errors and drift. A potentiometer is not required to obtain a zero output for zero input.

Figure 3. Normal-Mode Rejection of Dual Slope Converter

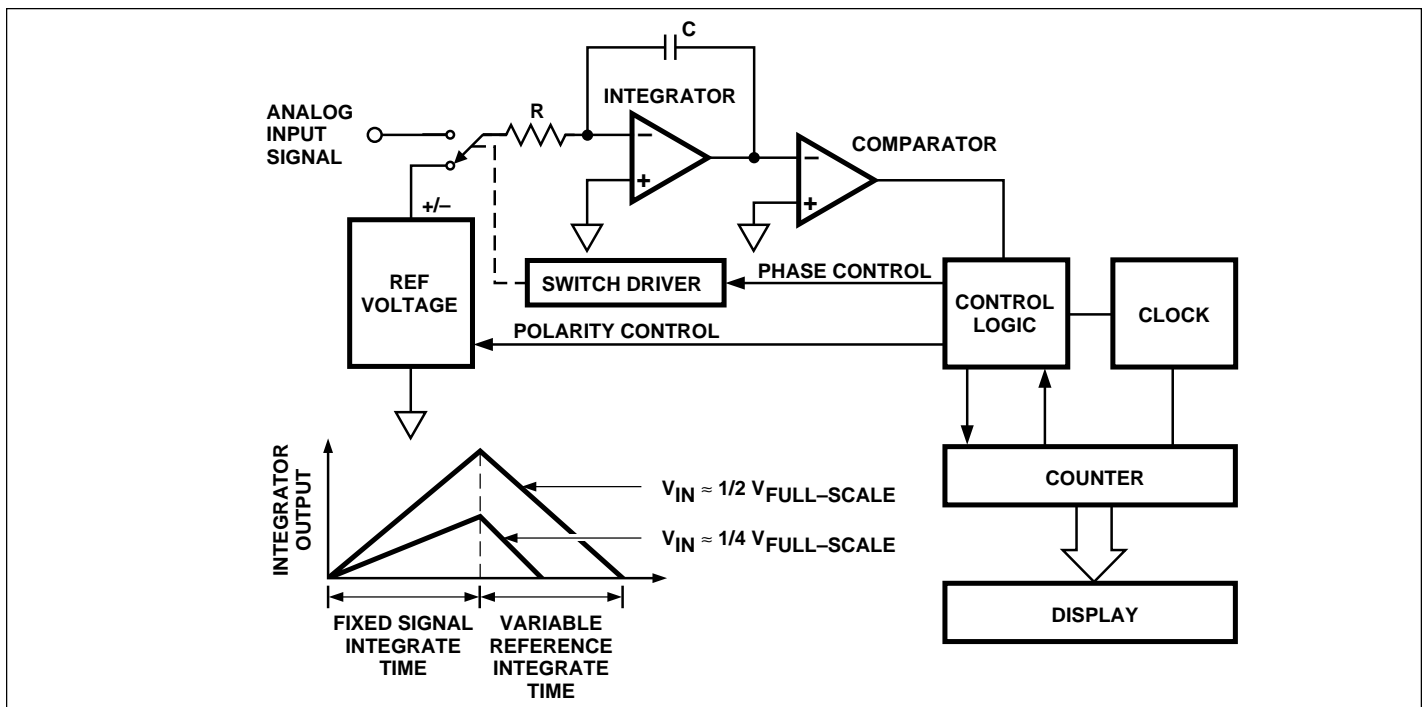

Figure 2. Basic Dual Slope Converter

THEORY OF OPERATION

Analog Section

In addition to the basic signal integrate and deintegrate cycles discussed above, the TC826 incorporates an auto-zero cycle. This cycle removes buffer amplifier, integrator, and comparator offset voltage error terms from the conversion. A true digital zero reading results without external adjusting potentiometers. A complete conversion consists of three cycles: an auto-zero, signal integrate and reference cycle. (Figures 4 and 5.)

Auto-Zero Cycle

During the auto-zero cycle the differential input signal is disconnected from the circuit by opening internal analog gates. The internal nodes are shorted to analog common (internal analog ground) to establish a zero input condition. Additional analog gates close a feedback loop around the

offset voltage error compensation. The voltage level established on CAZ compensates for device offset voltages.

The auto-zero cycle length is 19 counts minimum. Unused time in the deintegrate cycle is added to the auto-zero cycle.

Signal Integration Cycle

The auto-zero loop is opened and the internal differential inputs connect to +IN and -IN. The differential input signal is integrated for a fixed time period. The TC826 signal integration period is 20 clock periods or counts. The externally set clock frequency is divided by 32 before clocking the internal counters. The integration time period is:

$$\text{Where: } T_{SI} = \frac{32}{F_{OSC}} \times 20$$

F_{OSC} = External Clock Frequency

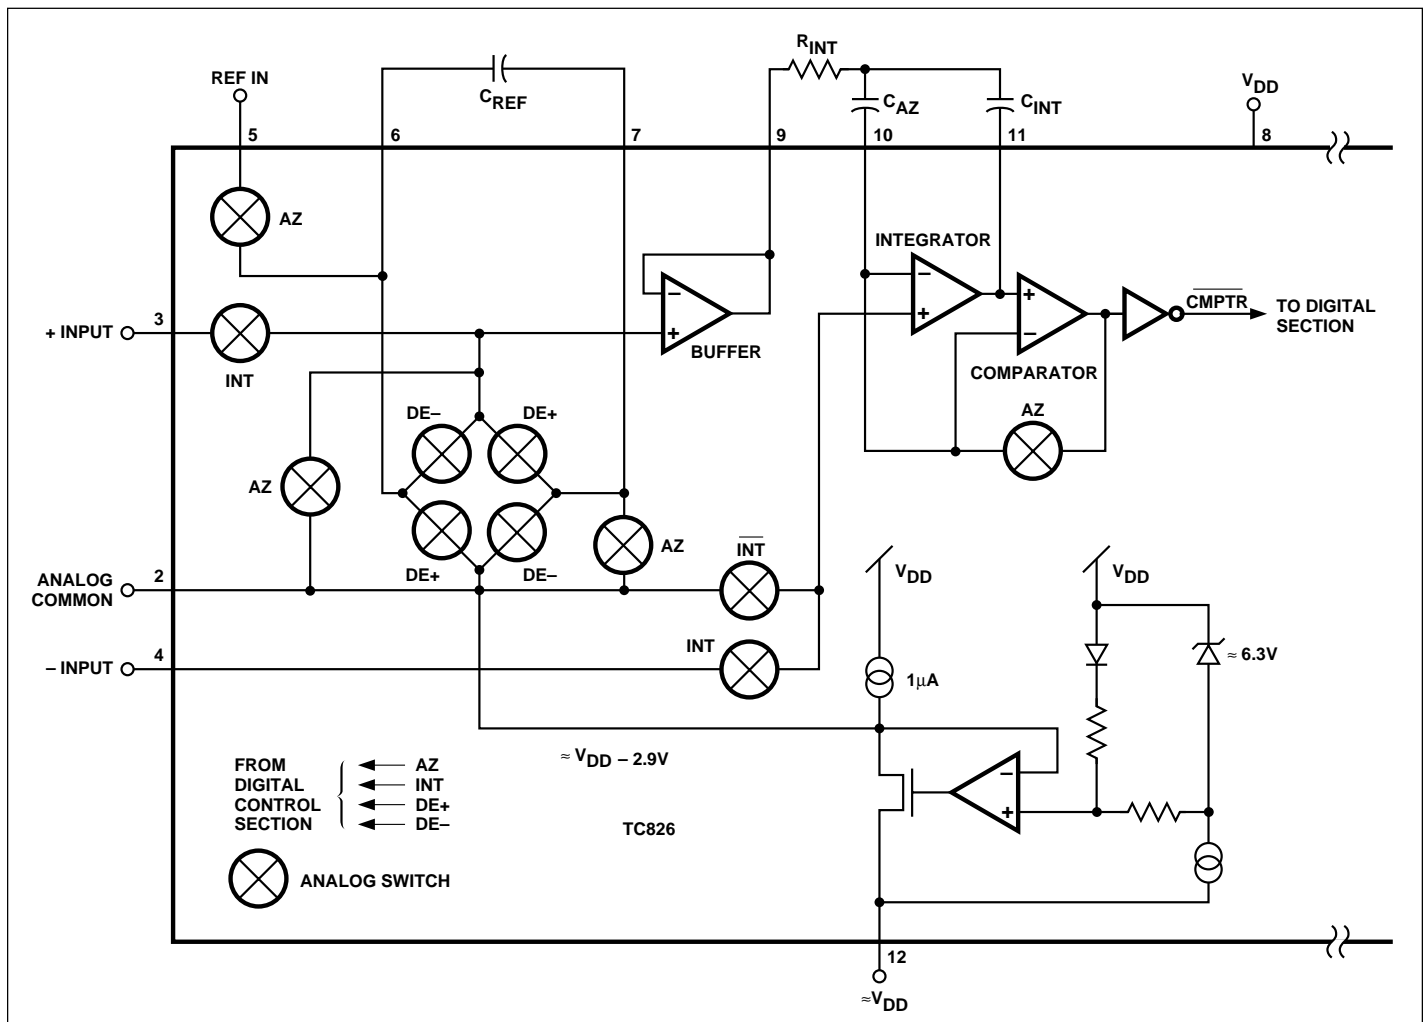

Figure 4. TC826 Analog Section

TC826

The differential input voltage must be within the device common-mode range when the converter and measured system share the same power supply common (ground). If the converter and measured system do not share the same power supply common, $-IN$ should be tied to analog-common. This is the usual connection for battery operated systems. Polarity is determined at the end of signal integrate phase. The sign bit is a true polarity indication in that signals less than 1 LSB are correctly determined. This allows precision null detection limited only by device noise and system noise.

Reference Integrate Cycle

The final phase is reference integrate or deintegrate. $-IN$ is internally connected to analog common and $+IN$ is connected with the correct polarity to cause the integrator output to return to zero. The time required for the output to return to zero is proportional to the input signal and is between 0 and 40 counts. The digital reading displayed is:

$$20 = \frac{V_{IN}}{V_{REF}}$$

System Timing

The oscillator frequency is divided by 32 prior to clocking the internal counters. The three phase measurement cycle

takes a total of 80 clock pulses. The 80 count cycle is independent of input signal magnitude.

Each phase of the measurement cycle has the following length:

- Auto-Zero Phase: 19 to 59 Counts
For signals less than full-scale the auto-zero is assigned the unused reference integrate time period.
- Signal Integrate: 20 Counts
This time period is fixed. The integration period is:

$$T_{SI} = 20 \left(\frac{32}{F_{OSC}} \right)$$

Where F_{OSC} is the externally set clock frequency.

- Reference Integrate: 0 to 41 Counts

Reference Voltage Selection

A full-scale reading requires the input signal be twice the reference voltage. The reference potential is measured between REF IN (Pin 5) and ANALOG COMMON (Pin 2).

Required Full-Scale Voltage	V_{REF}
20mV	10mV
2V	1V

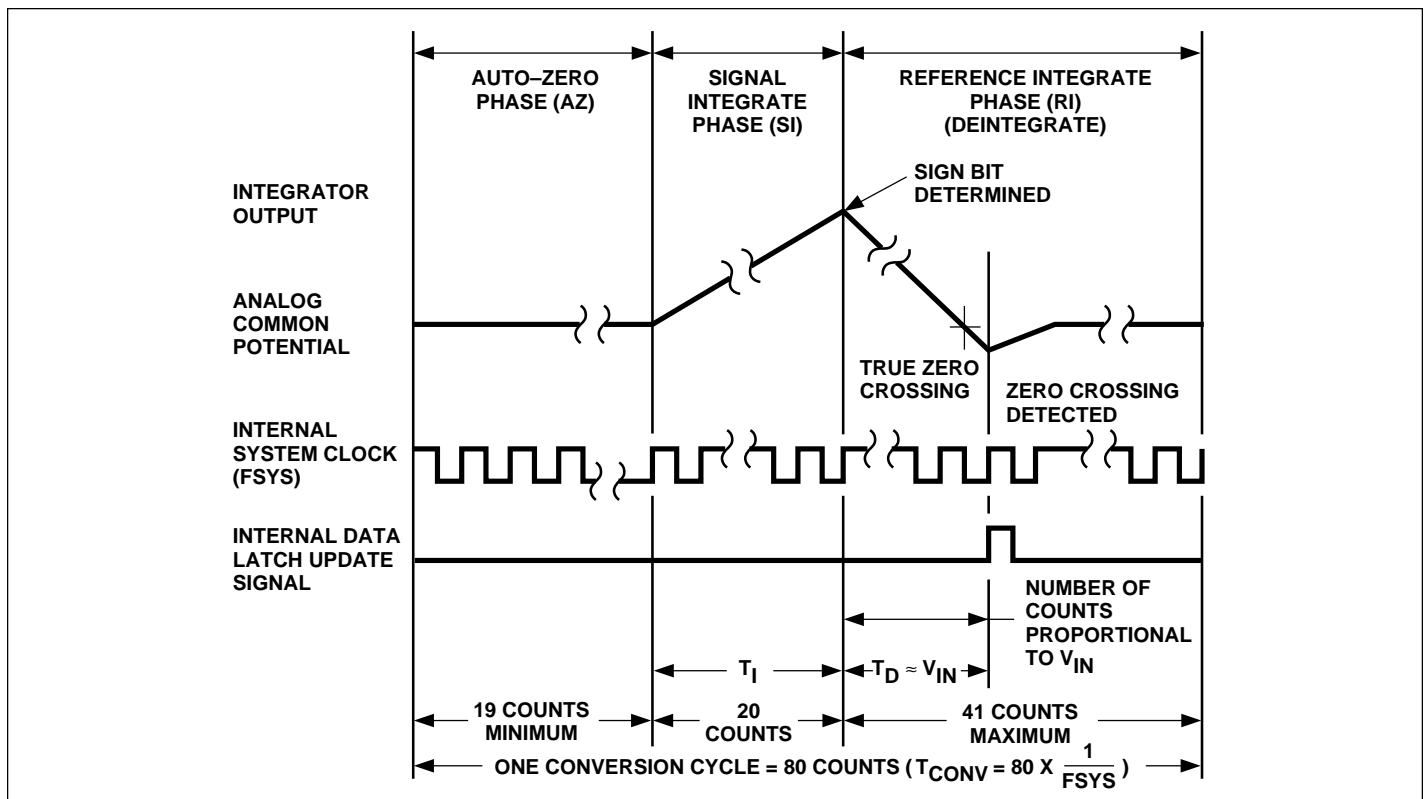

Figure 5. TC826 Conversion Has Three Phases

The internal voltage reference potential available at analog-common will normally be used to supply the converters reference. This potential is stable whenever the supply potential is greater than approximately 7V. In applications where an externally generated reference voltage is desired refer to Figure 6.

The reference voltage is adjusted with a near full-scale input signal. Adjust for proper LCD display readout.

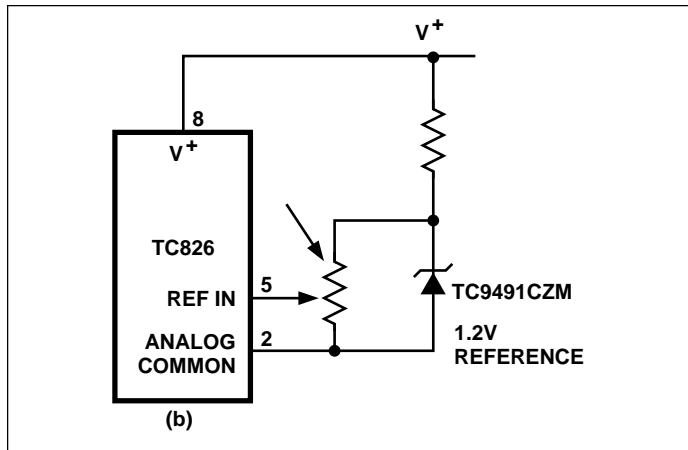

Figure 6. External Reference

Components Value Selection

Integrating Resistor (R_{INT})

The desired full-scale input voltage and output current capability of the input buffer and integrator amplifier set the integration resistor value. The internal class A output stage amplifiers will supply a $1\mu\text{A}$ drive current with minimal linearity error. R_{INT} is easily calculated for a $1\mu\text{A}$ full-scale current:

$$R_{INT} = \frac{\text{Full-Scale Input Voltage (V)}}{1 \times 10^{-6}} = \frac{V_{FS}}{1 \times 10^{-6}}$$

Where V_{FS} = Full-Scale Analog Input

Integrating Capacitor (C_{INT})

The integrating capacitor should be selected to maximize integrator output swing. The integrator output will swing to within 0.4V of V_S^+ or V_S^- without saturating.

The integrating capacitor is easily calculated:

$$C_{INT} = \frac{V_{FS}}{R_{INT}} \left(\frac{640}{F_{OSC} \times V_{INT}} \right)$$

Where : V_{INT} = Integrator Swing
 F_{OSC} = Oscillator Frequency

The integrating capacitor should be selected for low dielectric absorption to prevent roll-over errors. Polypropylene capacitors are suggested.

Auto-Zero Capacitor (C_{AZ})

C_{AZ} should be 2–3 times larger than the integration capacitor. A polypropylene capacitor is suggested. Typical values from $0.14\mu\text{F}$ to $0.068\mu\text{F}$ are satisfactory.

Reference Capacitor (C_{REF})

A $1\mu\text{F}$ capacitor is suggested. Low leakage capacitors such as polypropylene are recommended.

Several capacitor/resistor combinations for common full-scale input conditions are given in Table 1.

Table 1 Suggested Component Values

Component	2V Full-Scale $V_{REF} \approx 1\text{V}$	200 mV Full-Scale $V_{REF} \approx 100\text{ mV}$	20 mV Full-Scale $V_{REF} \approx 10\text{ mV}$
R_{INT}	2 M Ω	200k Ω	20k Ω
C_{INT}	0.033 μF	0.033 μF	0.033 μF
C_{REF}	1 μF	1 μF	1 F
C_{AZ}	0.068 μF	0.068 μF	0.14 μF
R_{OSC}	430k Ω	430k Ω	430k Ω

NOTES: Approximately 5 conversions/second.

Differential Signal Inputs

The TC826 is designed with true differential inputs and accepts input signals within the input stage common-mode voltage range (V_{CM}). The typical range is $V^+ -1$ to $V^- +1\text{V}$. Common-mode voltages are removed from the system when the TC826 operates from a battery or floating power source (Isolated from measured system) and $-IN$ is connected to analog-common (V_{COM}).

In systems where common-mode rejection ratio minimizes error. Common-mode voltages do, however, affect the integrator output level. Integrator output saturation must be prevented. A worse case condition exists if a large positive V_{CM} exists in conjunction with a full-scale negative differential signal. The negative signal drives the integrator output positive along with V_{CM} . For such applications, the integrator output swing can be reduced below the recommended 2V full-scale swing. The integrator output will swing within 0.3V of V_{DD} or V_{SS} without increased linearity error.

Digital Section

The TC826 contains all the segment drivers necessary to drive a liquid crystal display (LCD). An LCD backplane driver is included. The backplane frequency is the external clock frequency divided by 256. A 430k Ω R_{OSC} gets the backplane frequency to approximately 55Hz with a 5V nominal amplitude. When a segment driver is in phase with the backplane signal the segment is 'OFF'. An out-of-phase segment drive signal causes the segment to be 'ON' or

TC826

visible. This AC drive configuration results in negligible DC voltage across each LCD segment. This insures long LCD display life. The polarity segment drive, $\overline{\text{POL}}$, is 'ON' for negative analog inputs. If $+\text{IN}$ and $-\text{IN}$ are reversed this indicator would reverse. The TC826 transfer function is shown in Figure 7.

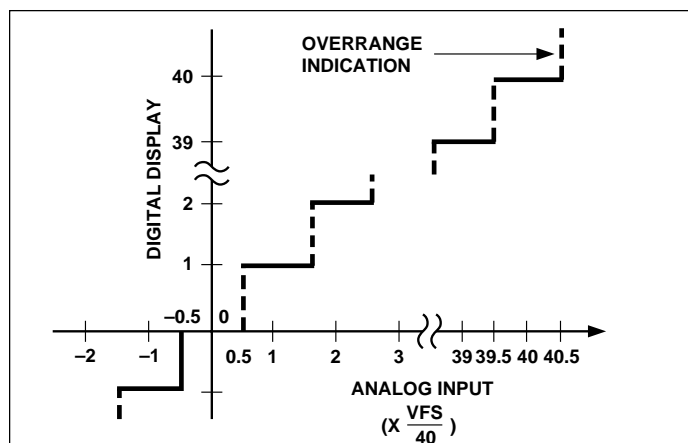

Figure 7. TC826 Transfer Function

BAR/DOT Input (Pin 61)

The $\overline{\text{BAR/DOT}}$ input allows the user to select the display format. The TC826 powers up in the BAR mode. Select the DOT display format by connecting $\overline{\text{BAR/DOT}}$ to the negative supply (Pin 12) through a $1\text{M}\Omega$ resistor.

HOLD Input (Pin 62)

The TC826 data output latches are not updated at the end of each conversion if $\overline{\text{HOLD}}$ is tied to the negative supply (Pin 12) through a $1\text{M}\Omega$ resistor. The LCD display continuously displays the previous conversion results.

The $\overline{\text{HOLD}}$ pin is normally pulled high by an internal pull-up.

TEST Input (Pin 63)

The TC826 enters a test mode with the $\overline{\text{TEST}}$ input connected to the negative supply (Pin 12). The connection must be made through a $1\text{M}\Omega$ resistor. The $\overline{\text{TEST}}$ input is normally internally pulled high. A low input sets the output data latch to all ones. The BAR display mode is set. The 41 LCD output segments (zero plus 40 data segments) and overrange annunciator flash on and off at $1/4$ the conversion rate. The polarity annunciator ($\overline{\text{POL}}$) segment will be on but not flashing.

Overtime Display Operation (OR, Pin 59)

An out-of-range input signal will be indicated on the LCD display by the OR annunciator driver (Pin 59) becoming active.

In the BAR display format the 41 bar segments and the overrange annunciator, OR, will flash ON and OFF. The flash rate is on fourth the conversion rate ($F_{\text{OSC}}/2560$).

In the DOT display mode, OR flashes and all other data segment drivers are off.

Polarity Indication (POL—Pin 60)

The TC826 converts and displays data for positive and negative input signals. The POL LCD segment driver (Pin 60) is active for negative signals.

Oscillator Operation

The TC826 external oscillator frequency, F_{OSC} , is set by resistor R_{OSC} connected between pins 13 and 14. The oscillator frequency versus resistance curve is shown in Figure 8.

Figure 8. Oscillator Frequency vs. R_{OSC}

F_{OSC} is divided by 32 to provide an internal system clock, F_{SYS} . Each conversion requires 80 internal clock cycles. The internal system clock is divided by 8 to provide the LCD backplane drive frequency. The display flash rate during an input out-of-range signal is set by dividing F_{SYS} by 320.

The internal oscillator may be bypassed by driving OSCI (Pin 13) with an external signal generator. OSC2 (Pin 14) should be left unconnected.

The oscillator should swing from V_{DD} to V_{SS} in single supply operation (Figure 9). In dual supply operation the signal should swing from power supply ground to V_{DD} .

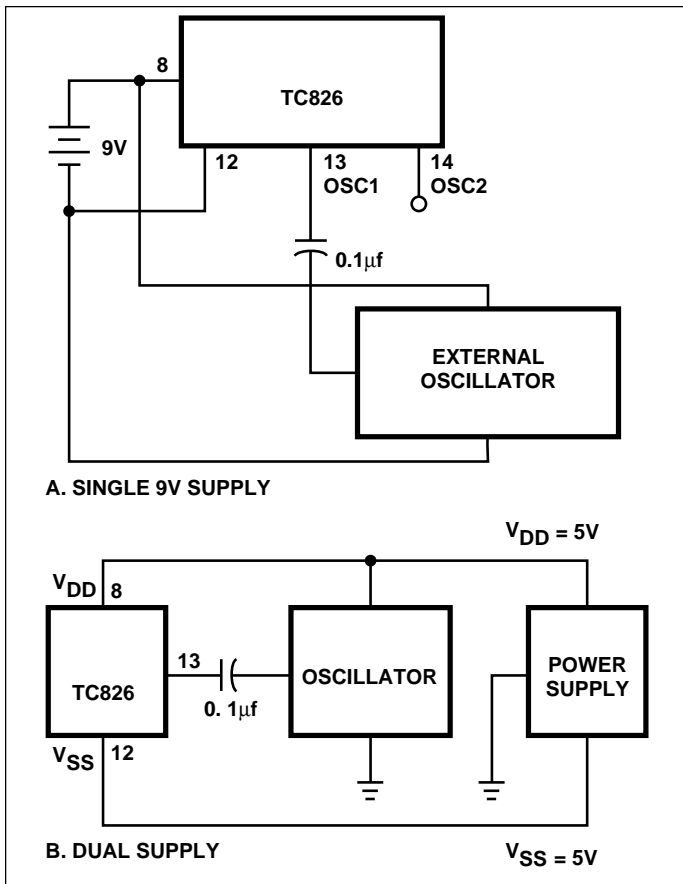

Figure 9. External Oscillator Connection

LCD Display Format

The input signal can be displayed in two formats (Figure 10). The BAR/DOT input (Pin 61) selects the format. The TC826 measurement cycle operates identically for either mode.

Figure 10. Display Option Formats

BAR Format

The TC826 power-ups in the BAR mode. BAR/DOT is pulled high internally. This display format is similar to a thermometer display. All bars/LCD segments, including zero, below the bar/LCD segment equaling the input signal level are on. A half-scale input signal, for example, would be displayed with BAR 0 to BAR 20 on.

DOT Format

By connecting BAR/DOT to VSS through a 1MΩ resistor the DOT mode is selected. Only the BAR LCD segment equaling the input signal is on. The zero segment is on for zero input.

This mode is useful for moving cursor or 'needle' applications.

TC826

LCD DISPLAYS

Most end products will use a custom LCD display for final production. Custom LCD displays are low cost and available from all manufacturers. The TC826 interfaces to non-multiplexed LCD displays. A backplane driver is included on chip.

To speed initial evaluation and prototype work a standard TC826 LCD display is available from Varitronix.

Varitronix Ltd. LCDs
4/F Liven House
61-63 King Yip Street
Kwun Tong, Kowloon
Hong Kong

Los Angeles, CA 90010
Tel: (213) 738-8700
Fax: (213) 738-5340

- Part No.: VBG-413-DP

Other standard LCD displays suitable for development work are available in both linear and circular formats. One manufacturer is:

UCE Inc.
24 Fitch Street
Norwalk, CT 06855
Tel: 203/838-7509

- Part No. 5040: 50 segment circular display with 3 digit numeric scale.
- Part No. 5020: 50 segment linear display.

LCD BACKPLANE DRIVER (PIN 15)

Additional drive electronics is not required to interface the TC826 to an LCD display. The TC826 has an on-chip backplane generator and driver. The backplane frequency is:

$$FBP = F_{OSC}/256$$

Figure 11 gives typical backplane driver rise/fall time versus backplane capacitance.

Figure 11. Backplane Driver Rise/Fall Time vs. Capacitance

FLAT PACKAGE SOCKET

Sockets suitable for prototype work are available. A USA source is:
